1. Introduction

This document describes the REST API endpoints provided by ICANN to contracted parties and Country Code Top-Level Domain (ccTLD) registries in order to retrieve monitoring and other information that is intended to be available only to the specific registry or registrar.

1.1. Date and Time

All the fields that represent dates in this document must contain timestamps indicating the date and time in Coordinated Universal Time (UTC).

1.2. Credentials

The MoSAPI uses the same credentials (e.g., username, password, list of IP address blocks - IPv4 and/or IPv6) as the Registration Reporting Interface (RRI). These credentials are managed through the NSP portal provided by ICANN to the contracted parties or through email in the case of ccTLD registries.

The MoSAPI supports both IPv4 and IPv6 transport.

The MoSAPI requires the use of Hypertext Transfer Protocol Secure (HTTPS) to provide confidentiality, server authentication, and integrity in the communication channel.

1.3. Glossary

In the following section, the concepts used in the MoSAPI are explained:

- **Service**: a service that may be monitored by the MoSAPI. The potential monitored services are: dns, rdds, epp and dnssec.

- **Test Cycle**: series of tests executed to verify the state of a monitored Service. For Domain Name System (DNS), the Service is considered to be up at a particular moment, if at least two of the delegated name servers registered in the DNS have successful results from tests to each of their public-DNS registered IP addresses in the root zone for the name server. For the Registration Data Directory Services Requirements (RDDS) Services (i.e. Whois tcp/43 and web-Whois) to be considered up at a particular moment, the Services must have successful results from tests to the randomly chosen public-DNS registered IP address to which whois.nic.<TLD> resolves. If 51% or more of the testing probe nodes see a monitored Service as unavailable at a given time, the Service will be considered unavailable. For RDDS, if any of the RDDS Services (i.e. Whois tcp/43 and web-Whois) is considered unavailable, the RDDS will be considered unavailable. The minimum number of active testing probe nodes to consider the results of a test cycle as valid at any given time is 20 for DNS and 10 for RDDS; otherwise the test cycle results will be discarded, and the Service will be considered up.
• **Test**: for DNS it means one non-recursive DNS query sent to a particular IP address via UDP or TCP; if DNSSEC is offered in the queried DNS zone, for a query to be considered answered, the signatures must be positively verified against a corresponding DS record published in the parent zone. For RDDS it means one query sent to a particular IP address. The answer to the query must contain the corresponding information from the Registry System, otherwise the query will be considered unanswered. A query with a RTT higher than X milliseconds will also be considered unanswered. For DNS (UDP) X=2,500 ms, DNS (TCP) X=7,500 ms for RDDS X=10,000 ms.

• **RTT (Round Trip Time)**: for DNS/UDP, the sequence of two packets, the UDP DNS query and the corresponding UDP DNS response. For DNS/TCP, the sequence of packets from the start of the TCP connection to its end. For Whois tcp/43, the sequence of packets from the start of the TCP connection to its end, including the reception of the Whois tcp/43 response. For web-Whois, the sequence of packets from the start of the TCP connection to its end, including the reception of a HTTP response; if the Registry Operator implements HTTP URL redirection (e.g. HTTP 302), only the last HTTP transaction is measured.

• **Emergency Threshold**: downtime threshold that if reached by any of the monitored Services may cause the TLD's Services emergency transition to an interim Registry Operator. To reach an Emergency Threshold a Service must accumulate X hours of total downtime during the last 7 days (i.e. rolling week). For DNS X=4, for RDDS X=24.

• **Incident**: an Incident is the collection of measurements from the moment an Alarm is generated until the moment that the Alarm is cleared. An Incident can have 2 distinct states:
  - Active: measurements corresponding to a current downtime.
  - Resolved: measurements corresponding to past downtime.

The measurements of Incidents that occurred in the last 7 days (i.e. rolling week, from: the current date and time -7days, to: the current date and time) are considered for the Service's Emergency Threshold calculations.

• **Alarm**: an Alarm signals that a Service has been detected as being down because X consecutive test cycles with Y minutes between them failed. An Alarm is cleared when the Service is detected as being up because X consecutive test cycles with Y minutes between them have been successful. For DNS, X=3 and Y=1. For RDDS, X=2 and Y=5. An alarmed Service triggers the creation of an Incident; if the Alarm is cleared then the Incident will be marked as resolved.

• **False Positive**: a flag set to an Incident indicating that an Incident was found by a manual process to be a false positive. When an Incident is marked as a False Positive the measurements of the Incident are not used for the Emergency Threshold calculations.
1.4. Technical requirements

- Clients shall use Transport Layer Security (TLS) version 1.3; only TLS 1.3 is supported by MoSAPI.
- Clients shall send the HTTP Cookies provided by the server on every HTTP request.
2. Common elements used in this specification

In the following section, common elements used in this specification are explained:

- `<base_url>`: the base URL of the MoSAPI is
  https://mosapi.icann.org/mosapi/<version>/<tld>, for example:
  https://mosapi.icann.org/mosapi/v1/example/monitoring/state

  Where:

  - `<version>` must be substituted by the version number of the specification supported
    by the server. For this specification its value must be ‘v1’.
  - `<tld>` must be substituted by the TLD being queried. In case of an IDN TLD, the A-
    label must be used.

- `<service>` must be substituted by the Service being queried. The possible values of
  Service, as described in Section 1 of gTLD Base Registry Agreement - Specification 10,
  are: dns, dnssec, rdds, and epp.
3. Session handling

The MoSAPI provides two endpoints for session handling, the authentication mechanism is HTTP Basic Access Authentication as specified in RFC 2617.

Authentication credentials for the API endpoints are provided by ICANN per TLD. The credentials must only be used when creating a session using the `<base_url>/login` API endpoint described in this section.

3.1. Creating a session

`<base_url>/login`

Possible results:

- HTTP/401, the `<base_url>/login` API endpoint provides a HTTP/401 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Invalid credentials" when the authentication credentials are invalid.

- HTTP/403, the `<base_url>/login` API endpoint provides a HTTP/403 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Your IP address is not allowed to connect for this TLD" if the credentials are valid but the connecting IP address is not whitelisted for the specified `<tld>`.

- HTTP/429, the `<base_url>/login` API endpoint provides a HTTP/429 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "You reached the limit of login requests per minute" for the specified `<tld>`.

Note: Only connections originating from IP addresses whitelisted for the `<tld>` counts towards the limit. Connections originating from IP addresses not included in the whitelist are dropped without further validation. Currently, the rate-limit allows for two one login requests per minute every 300s per `<tld>`. Developers are encouraged to re-use the session to minimize the number of login requests.

- HTTP/200, when a valid request is received, the `<base_url>/login` API endpoint provides an HTTP/200 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Login successful". The HTTP header Set-Cookie is set with the cookie attributes "id=<sessionID>; expires=<date>; path=<base_url>; secure; httponly".

  - The `<sessionID>` value is a 160-bit random value encoded in Base16.
  - The `<date>` value is the expiration date of the session.

Example using curl (https://curl.haxx.se/) for a login request:

```
curl --cookie-jar cookies.txt --user user:passwd https://mosapi.icann.org/mosapi/v1/example/login
```

Note: Every time the `<base_url>/login` API endpoint successfully validates the credentials and origin IP address, a new session is created. Only `4one` concurrent sessions are permitted per account. A session is only terminated after its expiration date (by default, the value
of expiration date is 15 minutes after the session is created), by using the <base_url>/logout API endpoint, or if the session is the oldest and a new session is being created that would be above the limit of permitted concurrent sessions.
3.2. Closing a session

In order to destroy a session, the client must set the HTTP header Cookie with the value "id=<sessionID>", where <sessionID> must be a 160-bit random value provided in the HTTP server response of a successful "login" request. If multiple cookies are provided, the first cookie is used for destroying the session.

Possible results:

- HTTP/401, the <base_url>/logout API endpoint provides a HTTP/401 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Invalid session ID" when the specified <sessionID> is invalid.

- HTTP/403, the <base_url>/logout API endpoint provides a HTTP/403 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Your IP address is not allowed to connect for this TLD" if the specified <sessionID> is valid but the connecting IP address is not whitelisted for the specified <tld>.

- HTTP/200, when a valid request is received, the <base_url>/logout API endpoint provides a HTTP/200 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Logout successful". The HTTP header Set-Cookie is set with the values "id=; expires=<date>; path=<base_url>; secure; httpOnly".
  
  - The <date> value is set to the Unix epoch date and time.
  - The <version> value must be 'v1'.
  - The <tld> value is the TLD being queried.

Example using CURL for a logout request:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/logout
4. API endpoint authentication

When sending a request to the MoSAPI, the client must set the HTTP header Cookie with the value "id=<sessionID>", where <sessionID> must be the 160-bit random value provided in the last HTTP server response of a successful "login" request. If multiple cookies are provided, the first cookie is used for validating the session.

The following responses may be provided by the API by the endpoints shown below:

- HTTP/401, the API endpoint provides a HTTP/401 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Invalid session ID" when the specified <sessionID> is invalid.

- HTTP/403, the API endpoint provides a HTTP/403 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Your IP address is not allowed to connect for this TLD" if the specified <sessionID> is valid but the connecting IP address is not whitelisted for the specified <tld>. 
5. gTLD Base Registry Agreement - Specification 10 monitoring

Registries may access the monitoring information collected by the SLA Monitoring system using the GET HTTP verb in the MoSAPI endpoints described below. The monitoring information will be refreshed at least every 2 minutes.

5.1. Monitoring the state of a TLD

<base_url>/monitoring/state

Possible results:

- HTTP/200, when a valid request is received, the <base_url>/monitoring/state API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "tld", a JSON string that contains the monitored TLD.

- "status", a JSON string that contains the status of the TLD as seen from the monitoring system. The "status" field may contain one of the following values:
  - Up: all of the monitored Services are up.
  - Down: one or more of the monitored Services are down.
  - Up-inconclusive: the SLA monitoring system is under maintenance, therefore all the monitored Services of the TLD are considered to be up by default.

  Note: if the status is "Up-inconclusive", all Services in the "testedServices" array will have the status with a value of "disabled".

- "lastUpdateApiDatabase", a JSON number that contains the Unix time stamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.

- "testedServices", a JSON array that contains detailed information for each potential monitored service (i.e. DNS, RDDS, EPP, DNSSEC). Each <service> object contains the following fields:
  - "status", a JSON string that contains the status of the Service as seen from the monitoring system. The "status" field can contain one of the following values:
    - Up: the monitored Service is up.
    - Down: the monitored Service is down.
    - Disabled: the Service is not being monitored.
    - UP-inconclusive-no-data: indicates that there are enough probe nodes online, but not enough raw data points were received to make a determination.
- UP-inconclusive-no-probes: indicates that there are not enough probe nodes online to make a determination.

  - "emergencyThreshold", a JSON number that contains the current percentage of the Emergency Threshold of the Service. Note: the value "0" specifies that there are no Incidents affecting the Emergency Threshold of the Service.

  - "incidents", a JSON array that contains "incident" objects. The "incident" object contains:
    - "incidentID", a JSON string that contains the Incident identifier (i.e. <incidentID>). The Incident identifier (i.e. <incidentID>) is a concatenation of the Unix time stamp of the start date and time of the Incident, followed by a full stop (".", ASCII value 0x002E), followed by the monitoring system identifier.
    - "startTime", a JSON number that contains the Unix time stamp of the start date and time of the Incident.
    - "falsePositive", a JSON boolean value that contains true or false with the False Positive status of the Incident.
    - "state", a JSON string that contains the current state (i.e. Active or Resolved) of the Incident.
    - "endTime", a JSON number that contains the Unix time stamp of the end date and time of the Incident; if the Incident state is active the "endTime" field will contain a null value.

Example using CURL to request the state of a TLD:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/monitoring/state
Example of a JSON response for a TLD state request:

```json
{
    "tld": "example",
    "lastUpdateApiDatabase": 1496923082,
    "status": "Down",
    "testedServices": {
        "DNS": {
            "status": "Down",
            "emergencyThreshold": "10.0000",
            "incidents": [{
                "incidentID": "1495811850.1700",
                "endTime": null,
                "startTime": "1495811850",
                "falsePositive": false,
                "state": "Active"
            }]
        },
        "DNSSEC": {
            "status": "Down",
            "emergencyThreshold": "10.0000",
            "incidents": [{
                "incidentID": "1495811790.1694",
                "endTime": null,
                "startTime": "1495811790",
                "falsePositive": false,
                "state": "Active"
            }]
        },
        "EPP": {
            "status": "Disabled"
        },
        "RDDS": {
            "status": "Disabled"
        }
    },
    "version": 1
}
```
5.2. Monitoring the Alarm status of a Service

`<base_url>/monitoring/<service>/alarmed`

Possible results:

- HTTP/404, the `<base_url>/monitoring/<service>/alarmed` API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified `<service>` is not being monitored.

- HTTP/200, when a valid request is received, the `<base_url>/monitoring/<service>/alarmed` API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "lastUpdateApiDatabase", a JSON number that contains the Unix time stamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.

- "alarmed", a JSON string that contains one of the following values:
  - Yes: an Alarm exists for the Service.
  - No: an Alarm does not exist for the Service.
  - Disabled: the Service is not being monitored.

Example using CURL to request the Alarm status of a Service:

```
curl --cookie cookies.txt
https://mosapi.icann.org/mosapi/v1/example.monitoring/dns/alarmed
```

Example of a JSON response for a Service in Alarm status:

```
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "alarmed": "Yes"
}
```
5.3. Monitoring the availability of a Service

<base_url>/monitoring/<service>/downtime

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/downtime API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <service> is not being monitored.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/downtime API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:
  - "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".
  - "lastUpdateApiDatabase", a JSON number that contains the Unix time stamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.
  - "downtime", a JSON number that contains the number of minutes of downtime of the Service during a rolling week period.

Example using CURL to request the availability of a Service:

```
curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/downtime
```

Example of a JSON response for a Service availability request:

```
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "downtime": 935
}
```
5.4. Query a list of Incidents for a Service

`<base_url>/monitoring/<service>/incidents?startDate=<startDate>&endDate=<endDate>&falsePositive=<falsePositive>`

Where:

- Optional `<startDate>` to be substituted by the Unix time stamp of the 'after' date and time to filter by. The filter will match Incidents that started after the provided date and time.

- Optional `<endDate>` to be substituted by the Unix time stamp of the 'before' date and time to filter by. The filter will match Incidents that started before the provided date and time.

- Optional `<falsePositive>` to be substituted by true or false in order to filter the Incidents marked as False Positive. If its value equals true, only Incidents marked as False Positive will be returned. If its value equals false, only Incidents not marked as False Positive will be returned. If `<falsePositive>` is not defined, all Incidents will be returned.

**Note:** The `<base_url>/monitoring/<service>/incidents` supports a maximum of 31 days difference between `<startDate>` and `<endDate>`. If only `<startDate>` is provided, the API endpoint will return results that are within 31 days after the date and time provided. If only `<endDate>` is provided, the API endpoint will return results that are within 31 days before the date and time provided. If neither `<startDate>` nor `<endDate>` are provided, the API endpoint will return results that are within 31 days before the current date and time. If `<endDate>` is in the future, the value of `<endDate>` will be the current date and time.

**Possible results:**

- HTTP/400, see section 8.

- HTTP/404, the `<base_url>/monitoring/<service>/incidents` API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified `<service>` is not being monitored.

- HTTP/200, when a valid request is received, the `<base_url>/monitoring/<service>/incidents` API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "lastUpdateApiDatabase", a JSON number that contains the Unix time stamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.

- "incidents", JSON array, see definition in section 5.1.
Example using CURL to request a list of Incidents of a Service:

```
curl --cookie cookies.txt
https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/incidents?startDate=1422492400&endDate=1422493000
```

Example of a JSON response showing a list of Incidents:

```json
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "incidents": [
        {
            "incidentID": "1422492450.699",
            "startTime": 1422492450,
            "falsePositive": false,
            "state": "Active",
            "endTime": null
        },
        {
            "incidentID": "1422492850.3434",
            "startTime": 1422492850,
            "falsePositive": true,
            "state": "Resolved",
            "endTime": 1422492950
        }
    ]
}
```
5.5. Monitoring the state of a particular Incident

\[ \text{<base_url>}/monitoring/<service>/incidents/<incidentID>/state \]

Where:

- <incidentID> must be substituted by the Incident id assigned by the monitoring system.

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/incidents/<incidentID>/state API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <incidentID> does not exist or if the specified <service> is not being monitored.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/incidents/<incidentID>/state API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "lastUpdateApiDatabase", a JSON number that contains the Unix timestamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.

- "incidents", JSON array, see definition in section 5.1.

Example using CURL to request the state of an Incident:

```
curl --cookie cookies.txt
https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/incidents/1422492450.699/state
```

Example of a JSON response for an Incident state request:

```
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "incidents": [
        {
            "incidentID": "1422492450.699",
            "startTime": 1422492450,
            "falsePositive": false,
            "state": "Active",
            "endTime": null
        }
    ]
}
```
5.6. Monitoring the False Positive flag of an Incident

<base_url>/monitoring/<service>/incidents/<incidentID>/falsePositive

Where:

- `<incidentID>` must be substituted by the Incident id assigned by the monitoring system.

Possible results:

- HTTP/404, the `<base_url>/monitoring/<service>/incidents/<incidentID>/falsePositive API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified `<incidentID>` does not exist or if the specified `<service>` is not being monitored.

- HTTP/200, when a valid request is received, the `<base_url>/monitoring/<service>/incidents/<incidentID>/falsePositive API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "lastUpdateApiDatabase", a JSON number that contains the Unix time stamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.

- "falsePositive", a JSON boolean value that contains true or false with the False Positive status of the Incident. The default value is false.

- "updateTime", a JSON number that contains the Unix time stamp of the date and time the False Positive status was updated; if the False Positive status has never been updated the "updateTime" field will contain a null value.

Example using CURL to request the False Positive flag of an Incident:

curl --cookie cookies.txt
https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/incidents/1422492930.699/falsePositive

Example of a JSON response for an Incident flagged as False Positive:

```
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "falsePositive": true,
    "updateTime": 1422494780
}
```
Note: The False Positive flag is the only thing that may change after an Incident is resolved. The user MAY be notified if an Incident is marked as a false positive by an offline mechanism.
5.7. Querying the list of measurements for an Incident

<base_url>/monitoring/<service>/incidents/<incidentID>

Where:

- <incidentID> must be substituted by the Incident id assigned by the monitoring system.

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/incidents/<incidentID> API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <incidentID> does not exist or if the specified <service> is not being monitored.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/incidents/<incidentID> API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "lastUpdateApiDatabase", a JSON number that contains the Unix time stamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.

- "measurements", a JSON array that contains a list of <measurementID> values assigned by the monitoring system. A <measurementID> is a concatenation of the Unix time stamp of the date and time when the measurement was computed, followed by a full stop (".", ASCII value 0x002E), followed by a random value, followed by a full stop (".", ASCII value 0x002E), followed by the string "json" (ASCII value, 0x006A + 0x0073 + 0x006F + 0x006E).

Example using CURL to request the list of measurements of an Incident:

curl --cookie cookies.txt
https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/incidents/1422492930.699

Example of a JSON response showing a list of measurements identifiers:

```json
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "measurements": [ 
        "1422492930.699.json",
        "1422492990.699.json",
        "1422493050.699.json",
        "1422493110.699.json"
    ]
}
```
5.8. Querying the details of a particular measurement

<base_url>/monitoring/<service>/incidents/<incidentID>/<measurementID>

Where:

- `<incidentID>` must be substituted by the Incident id assigned by the monitoring system.
- `<measurementID>` must be substituted by the measurement id assigned by the monitoring system.

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/incidents/<incidentID>/<measurementID> API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified `<incidentID>` does not exist, the specified `<measurementID>` does not exist or if the specified `<service>` is not being monitored.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/incidents/<incidentID>/<measurementID> API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:
  - "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".
  - "lastUpdateApiDatabase", a JSON number that contains the Unix time stamp of the date and time that the monitoring information provided in the MoSAPI was last updated from the monitoring system central database.
  - "tld", a JSON string that contains the monitored TLD.
  - "service", a JSON string that contains the Service being queried. The possible values of Service, as described in Section 1 of Specification 10, are: dns, dnssec, rdds, and epp.
  - "cycleCalculationDateTime", a JSON number that contains the date and time the test cycle results were computed.
  - "status", a JSON string that contains the status of the Service after computing the test cycle results. The "status" field can contain one of the following values:
    - Up: the monitored Service is up.
    - Down: the monitored Service is down.
    - UP-inconclusive-no-data: indicates that there are enough probe nodes online, but not enough raw data points were received to make a determination.
    - UP-inconclusive-no-probes: indicates that there are not enough probe nodes online to make a determination.
- "testedInterface", a JSON array that contains information about the interface being tested. The "testedInterface" fields contains the following fields:
  o "interface", a JSON string that contains the tested interface.
  o "probes", a JSON array that contains detailed monitoring information per probe node. The "probes" field contains the following fields:
    - "city", a JSON string with the location the location of the probe node.
    - "status", a JSON string that contains the status of the interface as seen from the probe node. The "status" field can contain one of the following values:
      - Up: the monitored Service is up.
      - Down: the monitored Service is down.
      - Offline: the probe node is offline. Note: the probe node is not considered part of the probe node universe when calculating the rolling week thresholds.
      - No result: results from this probe node were not received by the central server when the calculations were executed. Note: the service is considered to be up for rolling week threshold calculations.
    - "testData", a JSON array that contains monitoring information. The "testData" field contains the following fields:
      + "target", a JSON string that in the case of the DNS Service contains the name server being tested, in the case of RDDS, this field contains "null".
      + "status", a JSON string that in the case of the DNS Service contains the status of the name server being tested. In the case of RDDS this field contains the status of the IP address being tested (available in the "metrics" element, see below). The "status" field contains the following fields:
        - Up: the test was considered successful.
        - Down: the test was not considered successful.
      + A "metrics", a JSON array with monitoring details of particular tests. The "metrics" field contains the following fields:
        - "testDateTime", a JSON number that contains the date and time the result was computed. If the "result" field contains "no data", the "testDateTime" field will contain a null value.
        - "targetIP", a JSON string with the IP Address being tested.
        - "rtt", a JSON number that contains the milliseconds needed for the query to be resolved. If the "result" field contains an error code or "no data", the "rtt" field will contain a null value.
        - "result", a JSON string that contains the value "ok" if the query response was valid, "no data" if no data was received from the probe node, or an error code if the result is not valid. The information
regarding the error codes may be found in section 5.8.1 and 5.8.2.
Note: in case of "no data" the query response is assumed to be valid for rolling week threshold calculations.

Note: the JSON object for the measurement details provides the status of the test cycle computed from the results of all probe nodes.

Example using CURL to request the details of a measurement:

curl --cookie cookies.txt

Example of JSON response for a DNS Service measurement details request:

```json
{
  "version": 1,
  "lastUpdateApiDatabase": 1422492450,
  "tld": "example",
  "service": "dns",
  "cycleCalculationDateTime": 1422734490,
  "status": "Up",
  "testedInterface": [
    {
      "interface": "DNS",
      "probes": [
        {

### 5.8.1. DNS/DNSSEC Monitoring error codes

The following table lists the error codes for DNS/DNSSEC monitoring:

<table>
<thead>
<tr>
<th>Result Code</th>
<th>Obsolete</th>
<th>Internal Error</th>
<th>Interface</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>N</td>
<td>Y</td>
<td>DNS UDP / DNS TCP</td>
<td>Internal error.</td>
</tr>
<tr>
<td>-2</td>
<td>N</td>
<td>Y</td>
<td>DNS UDP</td>
<td>Expecting NOERROR RCODE but got unexpected RCODE from local resolver.</td>
</tr>
<tr>
<td>-3</td>
<td>N</td>
<td>Y</td>
<td>DNS TCP</td>
<td>Expecting NOERROR RCODE but got unexpected RCODE from local resolver.</td>
</tr>
<tr>
<td>-200</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>No reply from the authoritative name server.</td>
</tr>
<tr>
<td>-201</td>
<td>Y</td>
<td>N</td>
<td>DNS UDP / DNS TCP</td>
<td>Invalid reply from Name Server.</td>
</tr>
<tr>
<td>-204</td>
<td>Y</td>
<td>N</td>
<td>DNS UDP / DNS TCP</td>
<td>DNSSEC error.</td>
</tr>
<tr>
<td>-206</td>
<td>Y</td>
<td>N</td>
<td>DNS UDP / DNS TCP</td>
<td>Keyset is not valid.</td>
</tr>
<tr>
<td>-207</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Expecting DNS class IN but got class CHAOS in the DNS response.</td>
</tr>
<tr>
<td>-208</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Expecting DNS class IN but got class HESIOD in the DNS response.</td>
</tr>
<tr>
<td>-209</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Expecting DNS class IN but got something different from class IN, CHAOS or HESIOD in the DNS response.</td>
</tr>
<tr>
<td>-210</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Header section incomplete in the DNS response.</td>
</tr>
<tr>
<td>-211</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Question section incomplete in the DNS response.</td>
</tr>
<tr>
<td>-212</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Answer section incomplete in the DNS response.</td>
</tr>
<tr>
<td>-213</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Authority section incomplete in the DNS response.</td>
</tr>
<tr>
<td>-214</td>
<td>N</td>
<td>N</td>
<td>DNS UDP</td>
<td>Additional section incomplete in the DNS response.</td>
</tr>
<tr>
<td>-215</td>

**Note:** the DNS resolvers used in the system validate DNSSEC.

**Note:** error codes marked as Obsolete are listed for documentation purposes.

**Note:** a test with an error code marked as an Internal Error will be considered to be UP.
6. Maintenance window support

The gTLD Base Registry Agreement allows the Registry Operator to inform ICANN of planned maintenance times. However, note that per the gTLD Base Registry Agreement, there is no provision for planned outages or similar periods of unavailable or slow service; any downtime, be it for maintenance or due to system failures, will be noted simply as downtime.

6.1. Common elements for maintenance window support

6.1.1. Schedule object

Registry operators use the schedule object to manage maintenance windows in the MoSAPI. The schedule object contains the following fields (required):

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".
- "name", a JSON string that contains a descriptive name of the maintenance window. The maximum length is 255 Unicode characters. Note: Unicode characters beyond the 255 limit will be ignored.
- "enable", a JSON boolean value that contains true when the maintenance window is enabled and false when the maintenance window is disabled.
- "description", a JSON string that contains a description of the maintenance window. The maximum length is 255 Unicode characters. Note: Unicode characters beyond the 255 limit will be ignored.
- "startTime", a JSON number that contains the date and time (specified in Unix timestamp) when the maintenance window starts being active.
- "endTime", a JSON number that contains the date and time (specified in Unix timestamp) when the maintenance window ends being active.

ICANN will suspend Emergency Escalation services only for the 10% Emergency Threshold alert for RDDS and EPP when an enabled ("enabled"=true) schedule object exist, and the threshold is reached on a time covered by the "startTime" and "endTime".

Example of a JSON schedule object:

```json
{
  "version": 1,
  "name": "load balancer upgrade",
  "enabled": true,
  "description": "The load balancer will be upgraded to version 3.4",
  "startTime": 1485941725,
  "endTime": 1486001764
}
```

6.1.2. Schedule object identifier

A schedule object is uniquely identified by a <scheduleID> identifier. The <scheduleID> is an UUID (as defined in RFC4122) generated by the user. The user defines the <scheduleID> identifier when creating the schedule object.
6.2. Creating or updating a schedule for a maintenance window

In order to create or update a schedule for a maintenance window, the user sends a schedule object using the PUT HTTP verb in the API endpoint provided at:

<base_url>/mntWin/<service>/<scheduleID>

Possible results:

- HTTP/400, see section 8.
- HTTP/404, the <base_url>/mntWin/<service>/<scheduleID> API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <service> does not exist.
- HTTP/200, the <base_url>/mntWin/<service>/<scheduleID> API endpoint provides a HTTP/200 status code if the API endpoint was able to receive the input, no syntax issue was found in the input, and the PUT verb was successful. The API endpoint sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "OK".

Example using CURL to create a maintenance window:

```
curl --cookie cookies.txt -H "Content-Type: application/json" https://mosapi.icann.org/mosapi/v1/example/mntWin/rdds/16beaa07-46a3-42eb-9e71-c2e06cfd8a9d -X PUT -d \
'{
  "enable": "true",
  "name": "Maintenance window for RDDS semester II-2017",
  "description": "Pre-planned maintenance window for RDDS",
  "startTime": "1512003600",
  "endTime": "1512006600",
  "version": "1"
}'
```
6.3. Deleting a schedule for a maintenance window

In order to delete a schedule for a maintenance window, the user must use the DELETE HTTP verb in the API endpoint provided at:

<base_url>/mntWin/<service>/<scheduleID>

Possible results:

- HTTP/400, see section 8.
- HTTP/404, the <base_url>/mntWin/<service>/<scheduleID> API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <scheduleID> does not exist or if the specified <service> does not exist.
- HTTP/200, the <base_url>/mntWin/<service>/<scheduleID> provides a HTTP/200 status code if the API endpoint was able to receive the input, no syntax issue was found in the input, and the DELETE verb was successful. The API endpoint sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "OK".

Example using CURL to delete a maintenance window:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/mntWin/rdds/16beaa07-46a3-42eb-9e71-c2e06cfd8a9b --X DELETE
6.4. Retrieving a schedule object for a maintenance window

In order to get the information of a schedule object, the user makes use of the GET HTTP verb in the following URL:

<base_url>/mntWin/<service>/<scheduleID>

Possible results:

- HTTP/400, see section 8.
- HTTP/404, the <base_url>/mntWin/<service>/<scheduleID> API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <scheduleID> does not exist or if the specified <service> does not exist.
- HTTP/200, the <base_url>/mntWin/<service>/<scheduleID> API endpoint provides a HTTP/200 status code if the API endpoint was able to receive the input, no syntax issue was found in the input, and the GET verb was successful. The API endpoint sets the HTTP header Content-type to "application/json; charset=utf-8". The schedule JSON object (see section 6.1.1) is provided in the HTTP Entity-body.

Example using CURL to request the details of a maintenance window:

```
curl --cookie cookies.txt
https://mosapi.icann.org/mosapi/v1/example/mntWin/rdds/16beaa97-46a1-42eb-9e71-c2e06cfd8a9b
```

Example of JSON response for a maintenance window details request:

```
{
   "enable": "true",
   "name": "Maintenance window for RDDS semester II-2017",
   "description": "Pre-planned maintenance window for RDDS",
   "startTime": "1512003600",
   "endTime": "1512006600",
   "version": "1"
}
```
6.5. Getting the list of maintenance windows that have not ended yet

In order to get a list of maintenance window identifiers (i.e. "scheduleID") that have not ended yet, the user make use of the GET HTTP verb in the API endpoint provided by ICANN at:

<base_url>/mntWin/<service>

Possible results:

- HTTP/404, the <base_url>/mntWin/<service>/<scheduleID> API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available if the specified <service> does not exist.

- HTTP/200, the <base_url>/mntWin/<service> API endpoint provides a HTTP/200 status code if the API endpoint was able to receive the input, and the GET verb was successful. The API endpoint sets the HTTP header Content-type to "application/json; charset=utf-8". A JSON array of schedule object identifiers is provided in the HTTP Entity-body.

Example using CURL to request the list of maintenance windows:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/mntWin/rdds

Example of a JSON array that contains the list of maintenance windows identifiers:

```json
{
  "schedules": [
    { "scheduleID": "7b2d3012-41f7-4bce-89e9-9a9b85575fa6" }
  ];
}
```
7. Probe node network

The current list of probe nodes used by the Monitoring System may be retrieved by using the GET HTTP verb in the API endpoint provided by ICANN at:

<base_url>/monitoring/nodes

Possible results:

- HTTP/200, when a valid request is received, the API provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "updateTime", a JSON number that contains the Unix time stamp of the date and time when the list was updated.

- "probeNodes", a JSON array that provides information per probe node. The "probeNodes" contains the following JSON objects:
  
  - "city", a JSON string that contains the location of the probe node.

  - "ipV4", a JSON string that contains the IPv4 address of the probe node. If a probe node does not support IPv4, the "ipV4" field will contain a null value.

  - "ipV6", a JSON string that contains the IPv6 address of the probe node. If a probe node does not support IPv6, the "ipV6" field will contain a null value.

Example using CURL to request the list of probe nodes:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/monitoring/nodes
Example of a JSON object that contains the list of probe nodes:

```json
{
    "version": 1,
    "updateTime": 1422492450,
    "probeNodes": [
        {
            "city": "Amsterdam",
            "ipV4": "192.0.2.3",
            "ipV6": "2001:DB8::3"
        },
        {
            "city": "Beijing",
            "ipV4": "192.0.2.4",
            "ipV6": null
        },
        {
            "city": "Boston",
            "ipV4": "192.0.2.5",
            "ipV6": "2001:DB8::5"
        },
        {
            "city": "Istanbul",
            "ipV4": "192.0.2.6",
            "ipV6": null
        },
        {
            "city": "WashingtonDC",
            "ipV4": "192.0.2.7",
            "ipV6": "2001:DB8::7"
        },
        {
            "city": "Sydney",
            "ipV4": "192.0.2.8",
            "ipV6": "2001:DB8::8"
        }
    ]
}
```
8. HTTP/400 extended error codes

The API endpoints provides a HTTP/400 if the input does not comply with the business rules or the syntax of the input is invalid. The API endpoint sets the HTTP header Content-type to "application/json; charset=utf-8". A JSON object with the fields listed below is provided in the HTTP Entity-body:

- "resultCode", a JSON number that contains the result code.
- "message", a JSON string that contains the standard error message defined in the table below.
- "description", a JSON string that may be used to provide additional error diagnostic information.

Example of a JSON object that contains extended error codes:

```json
{
  "resultCode":2001,
  "message":"The UUID syntax is incorrect",
  "description":"The UUID (ee69b727-2abb-4f1c-8208-e5e76zd758f) syntax is incorrect"
}
```
The following table contains the extended error codes for the HTTP/400 status:

<table>
<thead>
<tr>
<th>Result Code</th>
<th>API endpoints</th>
<th>HTTP Verb</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2001</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>• • •</td>
<td>The UUID syntax is incorrect.</td>
</tr>
<tr>
<td>2002</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The maintenance window start date and time is not 24 hours ahead of the current date and time.</td>
</tr>
<tr>
<td>2003</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The period specified by start and end date and time is greater than the monthly SLR for the service.</td>
</tr>
<tr>
<td>2004</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The period specified in the maintenance window collides with a previously scheduled maintenance window for the service.</td>
</tr>
<tr>
<td>2005</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>• • •</td>
<td>The maintenance window functionality is disabled for this TLD.</td>
</tr>
<tr>
<td>2006</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The maintenance window that you are trying to delete already started.</td>
</tr>
<tr>
<td>2007</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The endTime is in the past, before or equal to the startTime.</td>
</tr>
<tr>
<td>2008</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The startTime syntax is incorrect.</td>
</tr>
<tr>
<td>2009</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The endTime syntax is incorrect.</td>
</tr>
<tr>
<td>2010</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The maintenance window that you are trying to update already ended, updates are not allowed.</td>
</tr>
<tr>
<td>2011</td>
<td>&lt;base_url&gt;/monitoring/&lt;service&gt;/incidents</td>
<td>•</td>
<td>The difference between endDate and startDate is more than 31 days.</td>
</tr>
<tr>
<td>2012</td>
<td>&lt;base_url&gt;/monitoring/&lt;service&gt;/incidents</td>
<td>•</td>
<td>The endDate is before the startDate.</td>
</tr>
<tr>
<td>2013</td>
<td>&lt;base_url&gt;/monitoring/&lt;service&gt;/incidents</td>
<td>•</td>
<td>The startDate syntax is incorrect.</td>
</tr>
<tr>
<td>2014</td>
<td>&lt;base_url&gt;/monitoring/&lt;service&gt;/incidents</td>
<td>•</td>
<td>The endDate syntax is incorrect.</td>
</tr>
<tr>
<td>2015</td>
<td>&lt;base_url&gt;/monitoring/&lt;service&gt;/incidents</td>
<td>•</td>
<td>The value of falsePositive is invalid.</td>
</tr>
<tr>
<td>2016</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The value of name or description cannot be blank.</td>
</tr>
<tr>
<td>2100</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The JSON syntax is invalid.</td>
</tr>
<tr>
<td>2101</td>
<td>&lt;base_url&gt;/mntWin/&lt;service&gt;/&lt;schedul eID&gt;</td>
<td>•</td>
<td>The maintenance window that you are trying to update already started, only enabled and endTime fields can be modified.</td>
</tr>
</tbody>
</table>
9. Domain Abuse Activity Reporting (DAAR)

ICANN's Domain Abuse Activity Reporting (DAAR) is a system for studying and reporting on domain name registration and security threat (domain abuse) behavior across top-level domain (TLD) registries and registrars. More information about the DAAR can be found at https://www.icann.org/octo-ssr/daar.

MoSAPI provides registries with access to DAAR-measurements for their TLDs using the GET and HEAD HTTP verbs in the MoSAPI endpoints described below. At the moment, DAAR data in MoSAPI is only available to gTLD registries.

9.1. Getting the latest DAAR report available for the TLD

<base_url>/daar/report/latest

Possible results:

- HTTP/404, the <base_url>/daar/report/latest API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body (only when using the HTTP/GET verb) with the string "Not available" if no report exists for the TLD.

- HTTP/200, when a valid request is received, the <base_url>/daar/report/latest API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". The header "Last-Modified" is set to the date and time when the report was generated.

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body (only when using the HTTP/GET verb):

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "2".

- "tld", a JSON string that contains the monitored TLD.

- "daarReportDate", a JSON string that contains the date of the report in the format <YYYY>-<MM>-<DD>. Where:
  - <YYYY>: year
  - <MM>: zero-padded month
  - <DD>: zero-padded day.

- "daarReportData", measurements of the DAAR reporting including the following elements (JSON strings): domains in zone, number of unique abuse domains, number of spam domains, number of phish domains, number of bot c&c domains and number of malware domains.

Example using CURL to request latest DAAR report:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/daar/report/latest
Example of a JSON response for the latest DAAR report:

```json
{
    "version": 1,
    "tld": "example",
    "daarReportDate": "2018-12-12",
    "daarReportData": {
        "domainsInZone": 27957,
        "uniqueAbuseDomains": 14,
        "spamDomains": 10,
        "phishDomains": 3,
        "botnetCcDomains": 0,
        "malwareDomains": 2
    }
}
```
9.2. Querying for a DAAR report for a date

<base_url>/daar/report/<YYYY>-<MM>-<DD>

Possible results:

- HTTP/404, the <base_url>/daar/report/<YYYY>-<MM>-<DD> API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body (only when using the HTTP/GET verb) with the string "Not available" if a report for the specified date does not exist.

- HTTP/200, when a valid request is received, the <base_url>/daar/report/<YYYY>-<MM>-<DD> API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the DAAR report (see section 9.1) is provided in the HTTP Entity-body (only when using the HTTP/GET verb).

  The header "Last-Modified" is set to the date and time when the report was generated.

Example using CURL to request the details of a measurement:

Example of JSON response for the DAAR report for a date:

  See example in section 9.1.
9.3. Querying for DAAR reports available

\texttt{<base_url>/daar/reports?startDate=<startDate>&endDate=<endDate>}

Where:

- Optional \texttt{<startDate>} to be substituted by \texttt{<YYYY>-<MM>-<DD>} to match reports after the provided date and time. If \texttt{<startDate>} is omitted, the oldest available report will match.

- Optional \texttt{<endDate>} to be substituted by \texttt{<YYYY>-<MM>-<DD>} to match reports before the provided date and time. If \texttt{<endDate>} is omitted, it will be substituted with the current date.

Note: if both \texttt{<startDate>} and \texttt{<endDate>} are omitted, all available reports will match.

Possible results:

- HTTP/400, see section 8, only the following error codes apply: 2012, 2013 and 2014.

- HTTP/200, when a valid request is received, the \texttt{<base_url>/daar/reports?startDate=<startDate>&endDate=<endDate>} API endpoint provides a HTTP/200 status code and sets the HTTP header \texttt{Content-type} to "application/json; charset=utf-8".

If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body (only when using the HTTP/GET verb):

- "version", a JSON number that contains the version number of the JSON object intended for future upgrades of the specification; for this version the value will always be "1".

- "tld", a JSON string that contains the monitored TLD.

- "daarReports", a JSON array with all the reports available within the period.

The array contains JSON objects with the following elements:

- "daarReportDate", see section 9.1 for definition.

- "daarReportGenerationDate", date and time that the report was generated in the format specified in RFC 3339.

Example using CURL to request the details of a measurement:

\texttt{curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/daar/reports}
Example of a JSON response for a query of reports available:

```
{
    "version": 1,
    "tld": "example",
    "daarReports": [{
        "daarReportDate": "2018-12-12",
        "daarReportGenerationDate": "2018-12-13T23:20:50.52Z"
    },
    {
        "daarReportDate": "2018-12-13",
        "daarReportGenerationDate": "2018-12-13T23:20:51.52Z"
    }
}
```

Example of a JSON response when no reports are available for the queried period:

```
{
    "version": 1,
    "tld": "example",
    "daarReports": []
}
```
10. Recent Measurements

MoSAPI provides registries with access to measurements files for cycles marked as up or down using the GET or HEAD HTTP verbs in the MoSAPI endpoints described below. This functionality allows registries to obtain raw data regarding the tests performed by the monitoring system regardless of the cycle being part of an incident.

10.1. Querying years for which reports are available

<base_url>/monitoring/<service>/measurements

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/measurements API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <service> is not being monitored.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/measurements API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the years for which reports are available is provided in the HTTP Entity-body (only when using the HTTP/GET verb).

Example using CURL to request years for which reports are available:

```
curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/measurements
```

Example of JSON response of the years for which reports are available:

```json
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "years": ["2018", "2017", "2016"]
}
```

Example of a JSON response when no years are available for the monitored service:

```json
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "years": []
}
```
10.2. Querying months for which reports are available

<base_url>/monitoring/<service>/measurements/<YYYY>

Where:

- <YYYY>: year

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/measurements API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <service> is not being monitored or the <YYYY> does not exist in the source.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/measurements/<YYYY> API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the months for which reports are available is provided in the HTTP Entity-body (only when using the HTTP/GET verb).

Example using CURL to request years for which reports are available:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/measurements/<YYYY>

Example of JSON response of the months for which reports are available:

```json
{
  "version": 1,
  "lastUpdateApiDatabase": 1422492450,
  "months": ["06", "05", "04", "03", "02", "01"]
}
```

Example of a JSON response when no months are available for the monitored service and the <YYYY>:

```json
{
  "version": 1,
  "lastUpdateApiDatabase": 1422492450,
  "months ": []
}
```
10.3. Querying days for which reports are available

<base_url>/monitoring/<service>/measurements/<YYYY>/<MM>

Where:

- <YYYY>: year
- <MM>: zero-padded month

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/measurements API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <service> is not being monitored or the <YYYY>/<MM> does not exist in the source.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/measurements/<YYYY>/<MM> API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the days for which reports are available is provided in the HTTP Entity-body (only when using the HTTP/GET verb).

Example using CURL to request years for which reports are available:

```
curl --cookie cookies.txt
  https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/measurements/<YYYY>/<MM>
```

Example of JSON response of the days for which reports are available:

```
{
  "version": 1,
  "lastUpdateApiDatabase": 1422492450,
  "days": ["03", "02", "01"]
}
```

Example of a JSON response when no days are available for the monitored service and the <YYYY>/<MM>:

```
{
  "version": 1,
  "lastUpdateApiDatabase": 1422492450,
  "days": []
}
```
10.4. Querying for available measurements

<base_url>/monitoring/<service>/measurements/<YYYY>/<MM>/<DD>

Where:

- <YYYY>: year
- <MM>: zero-padded month
- <DD>: zero-padded day

Possible results:

- HTTP/404, the <base_url>/monitoring/<service>/measurements API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified <service> is not being monitored or the <YYYY>/<MM>/<DD> does not exist in the source.

- HTTP/200, when a valid request is received, the <base_url>/monitoring/<service>/measurements/<YYYY>/<MM>/<DD> API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the available measurements is provided in the HTTP Entity-body (only when using the HTTP/GET verb).

Example using CURL to request years for which reports are available:

curl --cookie cookies.txt https://mosapi.icann.org/mosapi/v1/example/monitoring/dns/measurements/<YYYY>/<MM>/<DD>

Example of JSON response of the days for which measurements are available:

```json
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "measurements": ["1422492930.json", "1422492990.json", "1422493050.json", "1422493110.json"]
}
```

Example of a JSON response when no measurements are available for the monitored service and the <YYYY>/<MM>/<DD>:

```json
{
    "version": 1,
    "lastUpdateApiDatabase": 1422492450,
    "measurements": []
}
```
10.5. Querying the details of a particular measurement

`<base_url>/monitoring/<service>/measurements/<YYYY>/<MM>/<DD>/<measurementID>`

Where:

- `<YYYY>`: year
- `<MM>`: zero-padded month
- `<DD>`: zero-padded day
- `<measurementID>` must be substituted by the measurement id assigned by the monitoring system.

Possible results:

- HTTP/404, the `<base_url>/monitoring/<service>/measurements/<YYYY>/<MM>/<DD>/<measurementID>` API endpoint provides a HTTP/404 status code, sets the HTTP header Content-type to "text/plain; charset=utf-8", and provides a text response in the HTTP Entity-body with the string "Not available" if the specified `<service>` is not being monitored or the `<measurementID>` does not exist in the source.

- HTTP/200, when a valid request is received, the `<base_url>/monitoring/<service>/measurements/<YYYY>/<MM>/<DD>/<measurementID>` API endpoint provides a HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8". If a valid request is received, a JSON object with the fields listed in section 5.8 is provided in the HTTP Entity-body.

  The Content-Encoding entity header is set to "gzip" indicating that the entity-body is compressed using the Lempel-Ziv coding (LZ77), with a 32-bit CRC.

- HTTP/406, when a valid request is received, the `<base_url>/monitoring/<service>/measurements/<YYYY>/<MM>/<DD>/<measurementID>` API endpoint provides a HTTP/406 if the client does not include a HTTP header Accept-Encoding with value set to "gzip".
11. List of ICANN-accredited Registrars’ RDAP Base URLs

The list of ICANN-accredited registrars’ RDAP base URLs may be retrieved by using the GET HTTP verb in the API endpoint provided at:

<base_url>/registrarRdapBaseUrl/list

Possible results:

- HTTP/200, when a valid request is received, the API provides an HTTP/200 status code and sets the HTTP header Content-type to "application/json; charset=utf-8".

  The header "Last-Modified" is set to the date and time when the list was generated from the data obtained from the system of record regardless of the existence of changes in the contents from a previous version of the list.

  If a valid request is received, a JSON object with the fields listed below is provided in the HTTP Entity-body:

  - "description", a JSON string that contains a description of the list; for this version the value to be used is: "ICANN-accredited Registrars’ RDAP base URL list".

  - "version", a JSON string that contains the version number of the JSON object intended for future upgrades of the specification; for this version, the value will always be "1.0".

  - "publication", a JSON string that contains the date and time specified in the format defined in RFC 3339 of the last change in the contents of the list.

  - "services", a JSON array with two elements: in order, an Entry Array and a Service URL Array.

    - The Entry Array contains all the IANA Registrar IDs that have the same set of base RDAP URLs based on the system of record.

      Note: currently, the system of record only allows setting one RDAP URL per IANA Registrar ID, but future updates may allow setting two or more RDAP base URLs. Future updates may also allow setting the RDAP base URL(s) for two or more IANA Registrar IDs.

    - The Service URL Array contains the list of base RDAP URLs usable for the entries found in the Entry Array.

      Note: the elements within these two arrays are not sorted in any way.

Example using CURL to request the list of probe nodes:

curl --cookie cookies.txt
https://mosapi.icann.org/mosapi/v1/example/registrarRdapBaseUrl/list
Example of a JSON object that contains the list of ICANN-accredited registrars' RDAP base URLs:

```json
{
    "description": "ICANN-accredited Registrars’ RDAP base URL list",
    "publication": "2019-05-01T21:00:05Z",
    "services": [
        [
            "645",
            "https://example.com/rdap/
        ],
        [
            "646",
            "https://nic.example/rdap/
        ]
    ],
    "version": "1.0"
}
```
12. Alternative methods of authentication

In addition to HTTP Basic Access Authentication, and state management using HTTP Cookies described in section 3 and 4, TLS Client Authentication is supported by MoSAPI as an alternative method of authentication and state management.

12.1. Overview

Nowadays it is common for a Registry Operator to subcontract the operation of Registry Services to one or more Registry Service Provider (RSP).

Before the implementation of TLS Client Authentication, the only mechanism of authentication was Basic Authentication with one set of credentials per TLD; therefore, an RSP wanting access to MoSAPI would have been forced to share the credentials with the Registry Operator. Thus, if credentials need to be changed, coordination between the RSP and Registry Operator is required.

RSPs have requested the ability to have separated credentials and additional authentication methods to access MoSAPI. Additionally, RSPs have requested a solution that allows them to change the credentials without going through the Registry Operator to execute such change.

RSPs have also expressed interest in using TLS Client Authentication, based on the experience of some RSPs using TLS Client Authentication in EPP.

12.2. TLS Client Authentication

As the name implies, this alternative method uses TLS with client authentication, meaning that MoSAPI will authenticate the client using X.509 certificates in HTTPS. TLSA DNS resource records (see RFC6698) are used to provide a mechanism to store the client certificates to be authenticated and authorized for a given TLD.

In order to setup TLS Client Authentication, the Registry Operator (logged with an account allowed to make changes for a TLD) needs to provide three pieces of information in the NSP portal:

1. Domain name for TLS Client access (e.g. rsp1.nic.example)
2. Authorized roles related to SLAM (more than one may be chosen):
   a. SLAM – Monitoring data captured by the SLAM (see, section 5 and 10)
   b. SLAM – DAAR data (see, section 9)
   c. SLAM – Registrar Base RDAP URL (see, section 11)
   d. SLAM – TLD Maintenance Window (see, section 6)
   e. SLAM – Technical Compliance Monitoring (for future use)
   f. SLAM – Probe node list

   Note: other authorized roles may be available in NSP, but they are not related to SLAM.
3. IP prefixes for whitelisting

MoSAPI uses the domain name for TLS access to find the TLSA RRs to be used to validate the client during the TLS handshake. A batch process, at least every hour, will query the DNS (validating with DNSSEC) to get the universe of TLSA RRs per owner name.
The following combinations of TLSA Certificate Usages Registry, TLSA Selectors and TLSA Matching Types are supported:

<table>
<thead>
<tr>
<th>TLSA Certificate Usages Registry</th>
<th>TLSA Selectors</th>
<th>TLSA Matching Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

### 12.3. Authentication and Authorization with TLS Client Authentication

MoSAPI will perform the following steps when authenticating and authorizing clients using TLS Client Authentication:

1. A client connects to MoSAPI and provides its certificate during the TLS handshake.
2. MoSAPI verifies that the universe of IP ACLs for whitelisting covers the source IP address of the client attempting the connection. HTTP/403 is returned to the client if this step fails.
3. MoSAPI verifies that the client certificate validates with any TLSA RR of the universe of TLSA RRs. If there is a match, the TLS connection is considered TLS-client authenticated. Otherwise, the TLS session is considered to be non-TLS-client authenticated; the client will still have the option to authenticate using HTTP Basic Access Authentication as before.
4. The client requests access to the SLAM monitoring data of a given TLD.
5. MoSAPI validates that the source IP is whitelisted specifically for the TLD. HTTP/403 is returned to the client if this step fails.

6.1 If the TLS connection is considered TLS-client authenticated, using the set of authorized TLSA RRs for the TLD, MoSAPI validates there is a match for the client certificate. In other words, MoSAPI validates that the client certificate is authorized for the TLD based on the roles permitted in NSP. HTTP/401 is returned to the client if this step fails.
6.2 If the TLS connection is considered non-TLS-client authenticated, HTTP cookies will be used to validate the session as described in sections 3 and 4 of this specification.

7. If client requests access to the monitoring data of another TLD, steps 5 and 6 are repeated.

Every time an HTTPS connection is established, a new session is created. Only 4 concurrent sessions are permitted per client certificate. A session is only terminated after its expiration date (by default, the value of expiration date is 4 hours after the session is created), or if the session is the oldest and a new session is being created, that would be above the limit of permitted concurrent sessions. When a session is terminated, the server closes the HTTPS connection.

The error codes HTTP/401 and HTTP/403 described in section 3.1 apply to this section.
